

PSC7475: Introduction to Causality

Lecture 1

Prof. Weldzius

Villanova University

Slides Updated: 2025-01-22

What is causal effect?

Factual vs. Counterfactual

- Does the minimum wage increase the unemployment rate?
 - Unemployment rate went up after the minimum wage increased
 - Would it have gone up if the minimum wage increase not occurred?
- Does having daughters affect a judge's rulings in court?
 - A judge with a daughter gave a pro-choice ruling.
 - Would they have done that if they had a son instead?
- Does race affect one's job prospect?
 - Jalen applied for a job but did not get it
 - Would Jalen have gotten that job if he were white?
- **Fundamental problem of causal inference:**
 - Can never observe counterfactuals, must be inferred.

Criminal record experiment

- Does having a criminal record affect job prospects?
- Experimental setting:
 - Randomly assign 4 hired “confederates” (2 White, 2 Black) to apply to different jobs in Milwaukee.
 - Men were matched on physical appearance, self-presentation, age, etc.
 - Confederates would alternate indicating they had a criminal record.
- Outcome of interest: receiving a callback from a potential employer.

A tale of two applications

	Criminal Record	Callback?
Applicant 1	Ex-felon	No
Applicant 2	No criminal record	Yes

- Did the first applicant not get a callback **because** they had a criminal record?

Notation and Jargon

- **Unit** (indexed by i): job application for employer
- **Treatment variable** T_i : criminal record or not
- **Treatment group** (treated units): applications with criminal record
- **Control group** (untreated units): applications without criminal record
- **Outcome variable** Y_i : callback

	T_i (ex-felon)	Y_i (callback)
Ex-felon applicant	1	0
Non-ex-felon applicant	0	1

Causal effects and counterfactuals

- What does “ T_i causes Y_i ” mean? \rightsquigarrow **counterfactuals**, “what if”
- Would an employer treat criminal & noncriminal applicants differently?
- Two **potential outcomes**:
 - $Y_i(1)$: would applicant i get a callback if applied as an ex-felon?
 - $Y_i(0)$: would applicant i get a callback if applied not as an ex-felon?
- **Causal effect**: $Y_i(1) - Y_i(0)$
 - $Y_i(1) - Y_i(0) = 0 \rightsquigarrow$ criminal record has no impact on callback
 - $Y_i(1) - Y_i(0) = -1 \rightsquigarrow$ criminal record prevents callback
 - $Y_i(1) - Y_i(0) = +1 \rightsquigarrow$ criminal record leads to callback

Potential Outcomes

	T_i (ex-felon)	Y_i (callback)	$Y_i(1)$	$Y_i(0)$
Ex-felon applicant	1	0	0	???
Non-ex-felon applicant	0	1	???	1

- **Fundamental problem of causal inference:**

- We only observe one of the two potential outcomes.
- Observe $Y_i = Y_i(1)$ if $T_i = 1$ or $Y_i = Y_i(0)$ if $T_i = 0$
- To infer causal effect, we need to infer the missing counterfactuals!

How can we figure out counterfactuals?

- Find a similar unit! \rightsquigarrow **matching** (Mill's method of difference)
- Did applicant fail to get a job offer because of his criminal record?
 - \rightsquigarrow find a non-ex-felon who is just like ex-felon applicant.
- NJ increased the minimum wage. Causal effect on unemployment?
 - \rightsquigarrow find a state similar to NJ that didn't increase minimum wage.

Imperfect matches

- The problem: imperfect matches!
- Say we match i (treated) and j (control)
- **Selection Bias:** $Y_i(1) \neq Y_j(1)$
- Those who take treatment may be different than those who take control.
- How can we correct for that?

Break time

- Space here for a break in the action

Changing minds on gay marriage

- Question: can we effectively persuade people to change their minds?
- Hugely important question for political campaigns, companies, etc.
- Psychological studies show it isn't easy.
- **Contact Hypothesis:** outgroup hostility diminished when people from different groups interact with one another.
- Today we'll explore this question the context of support for gay marriage and contact with a member of the LGBT community.
 - Y_i = support for gay marriage (1) or not (0)
 - T_i = contact with member of the LGBT community (1) or not (0)

Causal effects and counterfactuals

- What does “ T_i causes Y_i ” mean? \rightsquigarrow **counterfactuals**, “what if”
- Would citizen i have supported gay marriage if they had contact with a member of the LGBT community?
- Two **potential outcomes**:
 - $Y_i(1)$: would i have supported gay marriage if they **had** contact with a member of the LGBT community?
 - $Y_i(0)$: would i have supported gay marriage if they **didn't have** contact with a member of the LGBT community?
- **Causal effect** for citizen i : $Y_i(1) - Y_i(0)$
- **Fundamental problem of causal inference**: only one of the two potential outcomes is observable.

Sigma notation

- We will often refer to the **sample size** (number of units) as n .
- We often have n measurements of some variable: (Y_1, Y_2, \dots, Y_n)
- We often want sums: how many in our sample support gay marriage?

$$Y_1 + Y_2 + \dots + Y_n$$

- Notation is a bit clunky, so we often use the **Sigma notation**:

$$\sum_{i=1}^n Y_i = Y_1 + Y_2 + \dots + Y_n$$

- $\sum_{i=1}^n$ means sum each value from Y_1 to Y_n

Averages

- The **sample average** or **sample mean** is simply the sum of all values divided by the number of values.
- Sigma notation allows us to write this in a compact way:

$$\bar{Y} = \frac{1}{n} \sum_{i=1}^n Y_i$$

- Suppose we surveyed 6 people and 3 supported gay marriage:

$$\bar{Y} = \frac{1}{6}(1 + 1 + 1 + 0 + 0 + 0) = 0.5$$

Quantity of interest

- We want to estimate the average causal effects over all units:

$$\text{Sample Average Treatment Effect (SATE)} = \frac{1}{n} \sum_{i=1}^n (Y_i(1) - Y_i(0))$$

- Why can't we just calculate this quantity directly?
- What we can estimate instead:

$$\text{Difference in means} = \bar{Y}_{treated} - \bar{Y}_{control}$$

- $\bar{Y}_{treated}$: observed average outcome for treated group
- $\bar{Y}_{control}$: observed average outcome for control group
- When will the difference-in-means be a good estimate of the SATE?

Randomized control trials (RCTs)

- **Randomize control trial:** each unit's treatment assignment is determined by chance
 - e.g., flip a coin; draw red and blue chips from a hat; etc.
- Randomization ensures **balance** between treatment and control group.
 - Treatment and control group are identical **on average**
 - Similar on both observable and unobservable characteristics.
- Control group \approx what would have happened to treatment group if they had taken control
 - $\bar{Y}_{control} \approx \frac{1}{n} \sum_{i=1}^n Y_i(0)$
 - $\bar{Y}_{treated} - \bar{Y}_{control} \approx \text{SATE}$

Some potential problems with RCTs

- **Placebo effects:**

- Respondents will be affected by any intervention, even if they shouldn't have any effect

- **Hawthorne effects:**

- Respondents act differently just knowing that they are under study.

Balance checking

- Can we determine if randomization “worked”?
- If it did, we shouldn't see large differences between treatment and control group on **pretreatment variable**
 - Pretreatment variable are those that are unaffected by treatment
- We can check in the actual data for some pretreatment variable X
 - $\bar{X}_{treated}$: average value of variable for treated group
 - $\bar{X}_{control}$: average value of variable for control group
 - Under randomization, $\bar{X}_{treated} - \bar{X}_{control} \approx 0$

Multiple treatments

- Instead of 1 treatment, we might have multiple **treatment arms**:
 - Control condition
 - Treatment A
 - Treatment B
 - Treatment C, etc.
- In this case, we will look at multiple comparisons:
 - $\bar{Y}_{treated,A} - \bar{Y}_{control}$
 - $\bar{Y}_{treated,B} - \bar{Y}_{control}$
 - $\bar{Y}_{treated,A} - \bar{Y}_{treated,B}$
- If treatment arms are randomly assigned, these differences will be good estimators for each causal contrast.
